# **High Voltage SWITCHMODE®** Series **DPAK For Surface Mount Applications**

This device is designed for high-voltage, high-speed power switching inductive circuits where fall time is critical. It is particularly suited for 115 and 220 V SWITCHMODE applications such as switching regulators, inverters, motor controls, solenoid/relay drivers and deflection circuits.

- Lead Formed for Surface Mount Applications in Plastic Sleeves (No Suffix)
- Straight Lead Version in Plastic Sleeves ("-1" Suffix)
- Lead Formed Version in 16 mm Tape and Reel ("T4" Suffix)
- Reverse Biased SOA with Inductive Loads @  $T_C = 100$  °C
- Inductive Switching Matrix 0.5 to 1.5 Amp, 25 and 100°C...

t<sub>c</sub> @ 1.0 A, 100°C is 290 ns (Typ)

- 700 V Blocking Capability
- Switching and SOA Applications Information
- Electrically Similar to the Popular MJE13003

#### **MAXIMUM RATINGS**

Rating	Symbol	Value	Unit
Collector-Emitter Voltage	V <sub>CEO(sus)</sub>	400	Vdc
Collector-Emitter Voltage	V <sub>CEV</sub>	700	Vdc
Emitter Base Voltage	V <sub>EBO</sub>	9	Vdc
Collector Current — Continuous — Peak (1)	I <sub>C</sub>	1.5 3	Adc
Base Current — Continuous — Peak (1)	I <sub>B</sub>	0.75 1.5	Adc

## **SWITCHING TIMES NOTE**

In resistive switching circuits, rise, fall, and storage times have been defined and apply to both current and voltage waveforms since they are in phase. However, for inductive loads which are common to SWITCHMODE power supplies and hammer drivers, current and voltage waveforms are not in phase. Therefore, separate measurements must be made on each waveform to determine the total switching time. For this reason, the following new terms have been defined.

 $t_{sv}$  = Voltage Storage Time, 90%  $I_{B1}$  to 10%  $V_{clamp}$ 

 $t_{rv}$  = Voltage Rise Time, 10-90%  $V_{elamp}$ 

 $t_{fi}$  = Current Fall Time, 90–10%  $I_C$ 

 $t_{ti} = Current Tail, 10-2\% I_C$ 

 $t_c$  = Crossover Time, 10%  $V_{clamp}$  to 10%  $I_C$ 

An enlarged portion of the inductive switching waveforms is shown in Figure 7 to aid in the visual identity of these terms.

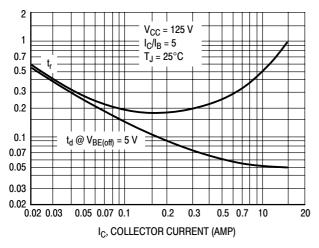

For the designer, there is minimal switching loss during storage time and the predominant switching power losses occur during the crossover interval and can be obtained using the equation:

$$P_{SWT} = 1/2 V_{CC}I_{C}(t_c)f$$

In general,  $t_{rv} + t_{fi} \approx t_c$ . However, at lower test currents this relationship may not be valid.

As is common with most switching transistors, resistive switching is specified at  $25^{\circ}$ C and has become a benchmark for designers. However, for designers of high frequency converter circuits, the user oriented specifications which make this a "SWITCHMODE" transistor are the inductive switching speeds ( $t_c$  and  $t_{sv}$ ) which are guaranteed at  $100^{\circ}$ C.

#### RESISTIVE SWITCHING PERFORMANCE

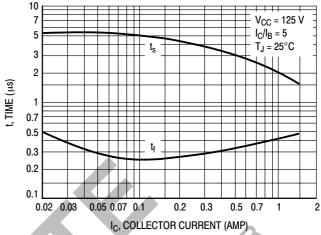

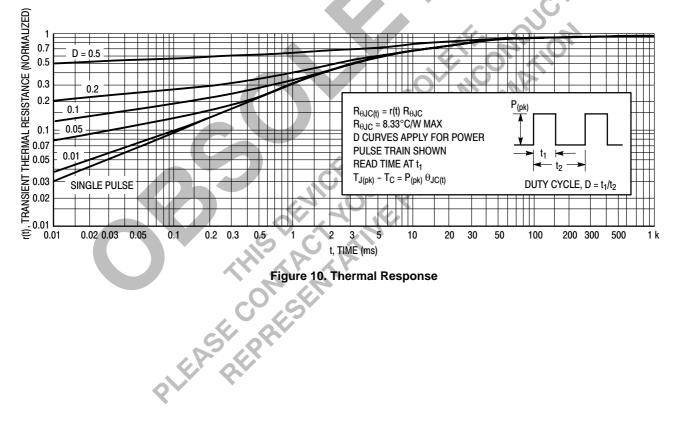

Figure 8. Turn-On Time

Figure 9. Turn-Off Time

The Sale Operating Area figures shown in Figures 11 and 12 are specified ratings for these devices under the test conditions shown.

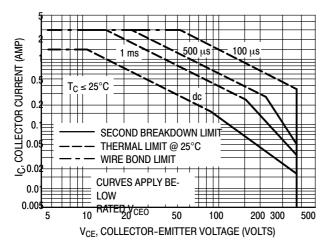

Figure 11. Active Region Safe Operating Area

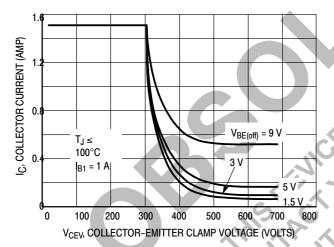

Figure 12. Reverse Bias Safe Operating Area

#### SAFE OPERATING AREA INFORMATION

#### FORWARD BIAS

There are two limitations on the power handling ability of a transistor: average junction temperature and second breakdown. Safe operating area curves indicate  $I_C - V_{CE}$  limits of the transistor that must be observed for reliable operation; i.e., the transistor must not be subjected to greater dissipation than the curves indicate.

The data of Figure 11 is based on  $T_C = 25^{\circ}C$ ;  $T_{J(pk)}$  is variable depending on power level. Second breakdown pulse limits are valid for duty cycles to 10% but must be derated when  $T_C \ge 25^{\circ}C$ . Allowable current at the voltages shown on Figure 11 may be found at any case temperature by applying curves on Figure 13.

 $T_{J(pk)}$  may be calculated from the data in Figure 10. At high case temperatures, thermal limitations will reduce the power that can be handled to values less than the limitations imposed by second breakdown.

#### REVERSE BIAS

For inductive loads, high voltage and high current must be sustained simultaneously during turn-off, in most cases, with the base to emitter junction reverse biased. Under these conditions the collector voltage must be held to a safe level at or below a specific value of collector current. This can be accomplished by several means such as active clamping, RC snubbing, load line shaping, etc. The safe level for these devices is specified as Reverse Bias Safe Operating Area and represents the voltage-current conditions during reverse biased turn-off. This rating is verified under clamped conditions so that the device is never subjected to an avalanche mode. Figure 12 gives RBSOA characteristics.
